This supplemental file is derived from the main data set to provide background to the associated concepts and methods of machine learning.

## Generation of machine learning models

A supervised learning was performed to select the best machine learning (ML)-models by categorizing individual instances in the train data set to established categories through the following steps:

## 1.) Acquisition of dataset and split into separate training and internal validation.

In total, 54 patients with MACS and 191 patients with non-functional adenomas completed a standardized 3-year follow-up to conclude the final diagnosis. Datasets were split into training and internal validation to estimate the perfomance of machine learning ( ML ) algorithms. $70 \%$ of data points were assigned to train the model and the remaining $30 \%$ were utilized to apply the trained model as internal test set. Randperm command in MatLab software was used to assure random splitting (supplementary figure 1 and supplementary table 2). Linear regression analysis was performed to determine the accuracy of dexamethason suppression test (DST). In parallel, feature selection was performed to reduces the dimensionality of the streoid data by selecting only a subset of measured steroids that provide the best predictive power in modeling the data set. The steroid profile data was tested using six feature selection methods supported by MatLab software (supplementary figure 2). Wilcoxon signed-rank test was eventually applied to select the 14 most useful steroids in this study

Supplementary Figure 1. Flowchart of data generation and the machine learning algorithm used for the prediction of MACS.

Supplementary figure 2. Results of feature selection of six different methods to determine a panel of 14 steroid profile with optimal performance on MACS patient discrimination from Excluded group.

## 2.Use of the training and validation datasets to inform a model of the relationship between features and target.

17 ML predictive models were generated using either cross-validation or resubstitution validation techniques (supplementary table 1). Due to small sample sizes of our study cohort, resubstitution validation was included in the process to minimize variability in the outcome. Two ML prediction models with the most optimal classification performance, the optimizable random tree and random undersampling (RUS) boosted tree were selected to generate the model prediction codes. Both models principally are designed to handle class imbalance problem in data with discrete class labels by using a combination of random sampling and boosting procedure. In each iteration, the perfomance of the algorithm in the training data is compared with the performance on the validation dataset (supplementary table 2, supplementary figure 3,supplementary figure 4). Significant differences on sensitivity, specificity and area under roc curve between dexamethasone suppression test and ML models in this phase were determined by p-values (supplementary table 4 and supplementary figure 3).

Supplementary table 1. Seventeen predictive models were used to generate ML-agorithms for prediction of MACS. Models are ranked and selected according to their accuracies.

| Predictive model | TP | FN | FP | TN | Sens | Spec | PPV | NPV | AUC | Accuracy |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## 3.Evaluation of the model via the external validation dataset to determine its prediction abilty for unseen instances.

A new set of data, containing 20 patients with MACS and 52 patients in whom the disease was excluded, was evaluated utilizing the established model prediction codes. Each individual prediction outcomes was compared to actual diagnosis to determine external validation model accuracy. Cutoff value of the prediction models were calculated using the mean rate of probablity values of each instances (supplementary table 3, supplementary figure 3,supplementary figure 4). P-values were calculated to denote significant differences on sensitivity, specificity and area under roc curve between dexamethasone suppression test and ML models (supplementary table 4 and supplementary figure 3).

Supplementary table 3. 72 patients ( 20 patients with MACS and 52 patients without MACS) were used to validate the models in external validation. Probability cut-off for each models were determined as mean value of each models.

|  | Diagnosis | Prob. [ACS] | Prob. [Excluded] | ML-2 | Prob. [ACS] | Prob. [Excluded] | ML-1 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Supplementary table 4. Comparison of sensitivities and specificities of dexamethason suppression test (DST) and machine learning models (ML-1 and ML-2) in training and validation steps.

## Optimizable tree (ML-1)

|  |  | Sensitivity (\%) |  |  | Specificity (\%) |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | n | DST | ML-1 | p-value | DST | ML-1 | p-value |
|  | 245 | 100 | 96 | 0.0561 | 83 | 94 | 0.0081 |
| Train-Test | 48 | 100 | 91 | 0,0341 | 16 | 95 | $<0,0001$ |
| Internal validation | 48 |  |  |  |  |  |  |
| External validation | 72 | 100 | 90 | 0.0307 | 53 | 94 | $<0,0001$ |

RUS Boosted tree (ML-2)

|  |  | Sensitivity (\%) |  |  | Specificity (\%) |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | n | DST | ML-2 | p-value | DST | ML-2 | p-value |
|  | 245 | 100 | 100 | 0.9987 | 83 | 96 | 0.0072 |
| Train-Test | 48 | 100 | 100 | 0.9992 | 16 | 92 | $<0,0001$ |
| External validation | 72 | 100 | 90 | 0.0237 | 53 | 82 | $<0,0001$ |

Supplementary figure 3. Comparison of area under curve (AUC) of dexamethason suppression test (DST) and steroid profile (SP) with machine learnings (ML-1 and ML-2) in training and validation steps.

Supplementary figure 4. Comparison of area under curve (AUC) of dexamethason suppression test (DST) and steroid profile (SP) with discriminant analyisis in training and validation steps
